Abstract: This paper aims to understand the behaviour of a carbon fiber/epoxy composite plate under the application of static pull loads through analytical method and the same was validated experimentally. In this paper effects of normal load on layers of different orientation have been studied. A MATLAB code was developed to determine the analytical solution for stresses and strains based on classical laminate theory[1, 6]. Experimental testing was done to validate the strain values in the direction of loading. Results of both analytical and experimental methods are compared.

Keywords: Composite Laminates, Composite Laminated Plate Theory, MATLAB

INTRODUCTION:

Composite materials are materials made from two or more constituent materials with significantly different physical or chemical properties, that when combined, produce a material with characteristics different from the individual components. Today, fiber reinforced composites are used in a variety of structures, ranging from spacecraft and aircraft to buildings and bridges. This wide use of composites has been facilitated by the introduction of new materials, improvements in manufacturing processes, and development of new analytical and testing methods. The applications of fiber-reinforced composites [7] over the past quarter-century have been primarily in specialty areas such as athletic equipment and aerospace structures. More recently, applications are developed in the infrastructure, including aircraft made up of composite materials. They have many advantages over conventional material; reduction in weight as they have low density, high strength, high performance and designable property. However the main problem is the reliability of material. Lots of analysis should be done first hand to know the behavior of the material under static and dynamic loading conditions. This paper aims to know the behavior of a carbon fiber/epoxy composite under the application of static tensile loads.

PROCEDURE:

A polymer matrix composite laminate made up of carbon fiber reinforcement and epoxy resin was analysed by experimental method. A MATLAB program was also developed to find out the analytical solution for the similar loading case. The laminate was prepared by resin infusion technique and its ends were tabbed using GFRP tabs. The final specimen was tested on INSTRON 8802 servo hydraulic UTM. Static tensile loads of different amplitudes were applied on the specimen. The load v/s displacement data was logged and compared with the analytical solution.

Experimental Evaluation :

Sample preparation: The material used is carbon fiber [IMA (equivalent of T800)] reinforced epoxy (RTM 120) composite which is made by Resin transfer moulding. The laminates layup sequence is [(+45/-45/0/90)S]s. A total of 16 layers are present in the laminate. The specimens are cut from large sheet with dimensions as 150 mm x 15 mm x 1.48 mm with help of a diamond cutter. The typical cure cycle of specimen is explained below and the curing graph is shown in fig 1 .

- Pre-pegs are removed from the cold storage at -18°C overnight before layup.
- Pre-pegs were cut as per requirement using automatic tape cutting machine.
- Layup was done at clean room.
- Typical autoclave cure process for monolithic part < 15mm (0.6”) thick is as under. The specimen with this process were manufactured at NAL, Bangalore.
  a) Apply full vacuum(1 bar).
  b) Apply 7 bar gauge autoclave pressure.
  c) Reduce vacuum to a safety value of -0.2 bar when the autoclave pressure reaches near 1 bar gauge.
d) Set heat up rate from room temperature to 180°C±5°C to achieve an actual component heat up rate between 1-2°C/minute.

e) Hold at 180°C±5°C for 120 minutes±5 minutes.

f) Cool component at an actual cool down rate of 2-4°C/minute.

g) Vent autoclave pressure when the component reaches 60°C or below.

h) Tabs of glass fiber reinforced epoxy composite, having size 40 mm x 15 mm x 3mm are attached to the specimens to achieve proper grip of the specimen in jaw. Tabs are joined by help of araldite and hardener. A photograph of the specimen with tabs is shown in figure 2.

**Figure 2 : Final Specimen**

**Test Equipment Details:**

All the tests were conducted on INSTRON8802. The machine has a load cell of 250 kN and its a servo hydraulic test system. The load cell can be auto tuned for different type of materials. It allows the user to perform Tensile, Compression, Bend, Fatigue, Fracture Toughness tests. In the current study tests were performed at room temperature and in laboratory air atmosphere. The specimen was fixed in wedge grips and the PID gains were automatically adjusted by the machine.

**Experimental Procedure:**

The load v/s displacement data of the specimen was acquired experimentally on INSTRON 8802 250 kN servo hydraulic test system. The specimen was gripped onto the machine with a gripping pressure of 2.5 bar. Different static loads were applied by the controller by increasing the load gradually. For each of the applied load corresponding displacement was logged using DAX software of INSTRON. The overall dimensions of the prepared laminate used for the experimental work is shown in fig 3.

**Figure 1: Curing graph**

**Analytical Solution :**

An analytical solution based on the classical laminated plate theory [1] was implemented to find stresses and strains on top bottom and mid plane of each layer in the composite laminate. The classical laminated plate theory is an extension of classical plate theory to laminated plates. In this theory the in-plane displacements are assumed to vary linearly through the thickness and transverse displacements are assumed to be constant through the thickness i.e. transverse strains are assumed to be zero.

The stresses and strains in any layer are calculated from the strains and curvature at the laminate mid plane. Firstly the elements of reduced stiffness matrix for the material are calculated from the material properties as follows:

\[
\begin{pmatrix}
\sigma_1 \\
\sigma_2 \\
\tau_{12}
\end{pmatrix} =
\begin{pmatrix}
Q_{11} & Q_{12} & 0 \\
Q_{12} & Q_{22} & 0 \\
0 & 0 & Q_{66}
\end{pmatrix}
\begin{pmatrix}
\varepsilon_1 \\
\varepsilon_2 \\
\gamma_{12}
\end{pmatrix}
\]

**Equation 1**

Where,

<table>
<thead>
<tr>
<th>Modulus of Elasticity (GPa)</th>
<th>Shear Modulus (GPa)</th>
<th>Poisson’s Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>E₁ 128</td>
<td>G₁₂ 4.8</td>
<td>ν₁₂ 0.31</td>
</tr>
<tr>
<td>E₂ 10</td>
<td>G₂₃ 3.2</td>
<td>ν₂₃ 0.52</td>
</tr>
<tr>
<td>E₃ 10</td>
<td>G₁₂ 4.8</td>
<td>ν₁₂ 0.31</td>
</tr>
</tbody>
</table>

**Table 1: Material Properties**
\[
Q_{11} = \frac{E_1}{1 - \nu_{12}^2} \quad Q_{22} = \frac{E_2}{1 - \nu_{21}^2} \\
Q_{12} = \frac{\nu_{12} E_2}{1 - \nu_{12}^2} \quad Q_{66} = G_{12}
\]

Then based on laminate code the transformed reduced stiffness matrix for each layer is calculated, which are required to find out the extensional, coupling and the bending stiffness matrix. The transformed reduced stiffness matrix for each layer is calculated as,

\[
T = \begin{bmatrix}
\cos^2\theta & \sin^2\theta & 2\sin\theta\cos\theta \\
\sin^2\theta & \cos^2\theta & -2\sin\theta\cos\theta \\
-\sin\theta\cos\theta & \sin\theta\cos\theta & \cos^2\theta - \sin^2\theta
\end{bmatrix}
\]

\[
R = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 2
\end{bmatrix}
\]

\[
\bar{Q} = [T]^T[Q][R][T][R]^T
\]

Where, \(\theta\) is the angle of fiber orientation in any particular layer. Then from the known loads \(N_i\), \(N_o\), \(M\), and mid-plane strains and curvature are found by solving the six simultaneous equations.

\[
N_x = \begin{bmatrix} A_1 & A_2 & A_3 & \cdots \end{bmatrix} \begin{bmatrix} \varepsilon_{x1} \\ \varepsilon_{x2} \\ \varepsilon_{x3} \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{13} & \cdots \end{bmatrix} \begin{bmatrix} K_{x1} \\ K_{x2} \\ K_{x3} \end{bmatrix}
\]

\[
N_{xy} = \begin{bmatrix} A_6 & A_7 & A_8 & \cdots \end{bmatrix} \begin{bmatrix} \gamma_{xy1} \\ \gamma_{xy2} \\ \gamma_{xy3} \end{bmatrix} + \begin{bmatrix} B_{61} & B_{62} & B_{63} & \cdots \end{bmatrix} \begin{bmatrix} K_{xy1} \\ K_{xy2} \\ K_{xy3} \end{bmatrix}
\]

\[
M_x = \begin{bmatrix} B_{11} & B_{12} & B_{13} & \cdots \end{bmatrix} \begin{bmatrix} \varepsilon_{x1} \\ \varepsilon_{x2} \\ \varepsilon_{x3} \end{bmatrix} + \begin{bmatrix} D_{11} & D_{12} & D_{13} & \cdots \end{bmatrix} \begin{bmatrix} K_{x1} \\ K_{x2} \\ K_{x3} \end{bmatrix}
\]

\[
M_{xy} = \begin{bmatrix} B_{61} & B_{62} & B_{63} & \cdots \end{bmatrix} \begin{bmatrix} \gamma_{xy1} \\ \gamma_{xy2} \\ \gamma_{xy3} \end{bmatrix} + \begin{bmatrix} D_{61} & D_{62} & D_{63} & \cdots \end{bmatrix} \begin{bmatrix} K_{xy1} \\ K_{xy2} \\ K_{xy3} \end{bmatrix}
\]

where \(\varepsilon_{x1}, \varepsilon_{xy1}\) are mid-plane strains and \(K_{x1}, K_{xy1}\) are mid-plane curvatures and

\[
A_{ij} = \sum_{k=1}^{n} \left( \bar{Q}_{ij} \right)_k (z_k - z_{k-1})
\]

\[
B_{ij} = \frac{1}{2} \sum_{k=1}^{n} \left( \bar{Q}_{ij} \right)_k (z_k^2 - z_{k-1}^2)
\]

\[
D_{ij} = \frac{1}{3} \sum_{k=1}^{n} \left( \bar{Q}_{ij} \right)_k (z_k^3 - z_{k-1}^3)
\]

where \(Z_k\) and \(Z_{k-1}\) are the distance of the \(K^{th}\) and \(K^{-1}\)th layer from the midplane respectively. From obtained mid-plane strains and curvatures strain components and corresponding stress components at any distance \(z\) from the mid-plane can be calculated.

Based on above inputs the code then calculates strains and stresses in global and local coordinates for top, middle and bottom plane of each layer.

The MATLAB code is extended to calculate the strain in z direction $\varepsilon_z$ by using the 6x6 stiffness matrix of transversely isotropic material and the normal strains in x and y direction for which the 5th material property i.e. transverse-transverse poisson's ratio (v_{23}) is required. $\varepsilon_z$ is calculated by substituting $\sigma_z=0$ (Plane Stress condition) as

$$ C_{11}\varepsilon_x + C_{23}\varepsilon_y + C_{22}\varepsilon_z = 0 $$

$$ \varepsilon_z = \frac{-C_{11}\varepsilon_x + C_{23}\varepsilon_y}{C_{22}} $$

Finally the analytical results were compared with experimental and finite element results.

**Results:**

**Experimental Results:** The experimental results were logged in the form of a stress – strain curve and results were logged. fig. 6 shows the stress strain relationship for the material. The stress-strain curve shows the relation between the applied stress level and corresponding strains in the direction of loading. The stress level was calculated by using the direct stress relation between force and area of cross section as

$$ \sigma = \frac{P}{A} $$

**Analytical Solution:**

Analytical results were obtained by the MATLAB code. The aforementioned load conditions, material properties and fiber orientation sequence were entered as input to the program, and calculated directional stresses and strains are presented.

Figure 4: Global Strain Distribution Through Laminate Thickness

Figure 5: Global Stress Distribution through Laminate Thickness
In Table 2 and 3 the strains and stresses are shown only for first 8 layers. Since the plate is symmetric [4, 5], the results are repeated symmetrically except for shear strain which are symmetric only in magnitude. These layer wise stress and strain distributions in global coordinates are shown in fig 4 and 5.

### Comparison with Experimental Results

To compare analytical solutions with experimental, similar graphs were created. In MATLAB, the stress-strain relation was computed by putting different load values within the desired range and corresponding strain in global y direction was noted. Fig 6 shows the analytical Stress-Strain curve.

![Figure 6: Comparison of Analytical and Experimental Results](image)

**CONCLUSIONS:**

It is observed that the values of shear strains are very low which theoretically should be zero. For layers of orientation 0° and 90°, shear stresses are also very low. This is because these layers are specially orthotropic as there is no coupling between normal stresses and shear strains and vice versa, which is obvious from the transformed reduced stiffness matrices for these layers (see program output) in which \( \overrightarrow{Q}_{16} \) and \( \overrightarrow{Q}_{26} \) are zero.

However for the angled plies (+45°, -45°) these terms in the transformed reduced stiffness matrix are non-zero, as a result of this coupling takes place between the normal and shearing terms of strains and stresses. Hence for these layers, shear stresses are non-zero even though the shear strains are zero. These layers are generally orthotropic laminae.

Fig. 6 shows that the stress-strain relationship is linear and show good congruence with experimental results. The error in strain obtained from analytical method at maximum load applied is 6.27%.
